

SUPPORTING AND CONNECTING A PORTABLE PHONE

FIELD OF THE INVENTION

The present invention relates generally to portable electronic device interfacing systems and processes. More particularly, the present invention relates to an apparatus and system for providing a mechanical and electrical interface between a universal interface module and a plurality of portable electronic devices having different physical configurations. The interface module can be located in an automobile, at home, in an office or in any other location where a power supply is available to allow access to features not offered by the portable electronic device alone. The portable electronic device may be a portable phone, portable computer, wireless data terminal or other wireless communication device or personal data assistant.

BACKGROUND OF THE INVENTION

Portable telephone systems have gained widespread acceptance as an efficient means of voice and data communications. While early mobile units were large and complex, miniaturization has made possible hand-held units with full functional telephony capabilities allowing the user freedom to use a phone in a mobile environment, such as in a vehicle or at a location remote from a hard wired connection to an existing telephony system. In addition, the cost of purchasing and using a portable phone has substantially declined and the quality and clarity of communication over a portable phone has increased causing

increased and widespread demand for portable phones by the public and resulting in the proliferation of multiple configurations of portable phones by many different manufacturers.

Unfortunately, the mobility and miniaturization of portable phones, together with the widespread adoption by the general public, has created practical issues for use of such phones. For example, the very use of the phone itself by the driver of a moving vehicle, i.e., dialing and conversing while holding the phone proximate his ear and mouth, raises safety issues for not only the driver but any passenger in the driver's vehicle as well as the occupants of other vehicles. In an attempt to solve this safety and convenience problem, portable phone manufacturers have made available car kits to allow for partial hands-free use of the phone. These kits include physical hardware to retain or mount the phone in the vehicle and a power cord to access the electrical system of the car for power rather than use the phone's battery and, in some instances, may also include attachments for connecting between the phone and a user headset or the car's audio speakers, a microphone and antenna. However, while these kits allow hands-free conversation, they do not allow hands-free dialing or operation of the phone and, unless a headset is being used by the driver, even the communication may be difficult if the phone is mounted in a location sufficiently removed from the driver that the internal microphone and speaker of the phone are inadequate. Moreover, if a headset is being used, the driver may be unable to hear emergency vehicle sirens, car horns or other important audible noises that contribute to safe driving.

Additionally, because there is a large variety of portable telephones in existence, each with its own unique mechanical, electrical and control interface, no single car kit can provide any form of universal connection among different phones and the power supply offered by

the electrical system of a vehicle. Thus, consumers must have a different kit for every different phone, a problem which is occurring with greater frequency due to rapidly increasing technical capabilities and performance in new phones and the decreasing cost of portable phones, and as different members of the same family acquire portable phones for their individual use. Similarly, automobile fleet users, such as large corporations, cannot provide a universal car kit connection for the variety of phones their employees may use and car rental companies cannot provide users with means to use their portable phones, or any other type of portable electronic device, in rented vehicles. Thus, users are forced to abandon their investment in the car kit when purchasing new models of telephones or users operate hand-held electronic devices while driving rather than purchasing an inadequate car kit for their car; an unsafe condition which is subject to increasing governmental concern and regulation.

Yet another issue raised by currently available phone mounting kits for cars is the adequacy of the mounting mechanism. Because space is a premium commodity in the passenger compartment of a vehicle, a phone mounting mechanism cannot be too large or too cumbersome. Depending upon where the mounting mechanism may be installed, i.e., on or under the dashboard or on the console between the front seats, space constraints may preclude certain types of mounting mechanisms. Moreover, vehicle safety requirements, such as have been promulgated by governmental agencies and telephone industry associations, require that any mechanism for mounting a portable phone in a vehicle be able to withstand impact forces up to twenty-five pounds in order to minimize the danger of the phone being dislodged in an accident and causing damage to an occupant of the vehicle.

4

Additionally, the mounting mechanism, whatever its configuration, must be able to withstand normal road vibrations without failure.

One attempt to address the foregoing problems is found in U.S. Patent 5,535,274 entitled Universal Connection For Cellular Telephone Interface. Therein, the inventors describe a mounting kit for a car which includes a common interface module and a pocket adapter. A portable phone mounts in the pocket and the pocket attaches to the interface module with a sliding movement along the longitudinal axis of the interface module. The pocket further includes an electrical connector which connects the internal electronics of the phone to the pocket. The interface module is electrically connected to the pocket by a flexible cord. Power for operating the phone and charging its battery is provided through the cord as is a connection to an external antenna. In addition, the interface module may include a microprocessor for managing communications with the phone and a memory device for storing operating parameters relating to the phone being used with the device. While this invention addresses certain of the foregoing issues, the interconnection between the pocket and the interface module can be improved. The sliding action for engagement of the retaining clip on the interface module by the latching assembly on the pocket member uses too much space. Moreover, it is unlikely that this mechanism dampens road vibrations or adequately secures the phone and pocket to the interface module during an impact.

Other efforts have been made to provide a latching mechanism that will withstand impact as well as road vibration, but these devices are also lacking. For example, U.S. Patent 5,189,358, entitled Adapter For Mounting Portable Radio Apparatus To Moving Body And Charger For Portable Radio Apparatus, describes a portable phone mount for use in a vehicle

where a retaining slot in the base of the phone first engages a lug in the adapter device and the phone is then rotated clockwise until the upper portion of the phone body engages a pair of ratchets in the mounting mechanism. While this mechanism may adequately secure the phone in the mount, the motion required to mount the phone is inefficient. It fails to minimize the use of space in the vehicle.

SUMMARY OF THE INVENTION

The present invention provides an improved mounting system for use with portable electronic devices, as well as an enhanced support system which not only facilitates use of the portable electronic device, but advantageously expands the features available to the user via the portable electronic device. As used herein, the term portable electronic device is intended to refer to not only portable phones, but portable computers, ham radio devices, other types of wireless communication devices, wireless data terminals and other types of personal data assistants (PDAs) .

The system includes a pocket member and an interface module. The interface module may be mounted in a vehicle or at any other location where it can be attached to a power source. The interface module connects to a pocket member through a universal or common mounting mechanism. The pocket member includes a receiving section for supporting and connecting to a portable electronic device such as a portable phone. Thus, while the receiving sections of pocket members will vary from one pocket member to another to accommodate portable electronic devices of different types and manufacturers, the mechanism for connecting a pocket member to the interface module will be common.

In this way, all pocket members can interface with an interface module, regardless of the type of portable electronic device and receiving section embodied in the pocket member. As a result, an interface module may be mounted at a single location, such as within a single vehicle, but used with a plurality of pocket members which support different portable electronic devices. In addition, a user may acquire multiple interface modules and place them at convenient locations, such as in a car, at home and at the office, and use a single pocket member in combination with each interface module.

The common mounting mechanism between the pocket member and the interface module is designed to optimize space utilization requirements. Rather than employing a sliding or rotational engagement between the pocket member and the interface module or some other complex motion which requires critical open space surrounding the mounting unit to accomplish a secure mounting of the portable electronic device in the vehicle, the present invention utilizes a limited, one dimensional motion to engage a latch mechanism between the pocket member and the interface module. As the pocket member is seated in the interface module using a short one dimensional movement of the pocket member, the latching mechanism moves from a first unengaged position to a second engaged position to secure the pocket member to the interface module. The latching mechanism includes one or more tabs which extend out of the interface module and into the pocket member to attain securement of the two components. In the preferred embodiment the tabs are offset such that they engage the pocket member sequentially rather than simultaneously. This reduces the amount of force needed to engage the tabs in the pocket member without compromising the strength of the engagement. The overall result is an improved latching mechanism that

requires a minimum amount of space to use and one that fully satisfies all government safety requirements regarding vehicle impact tests.

A further advantage of the present invention is that the interface module may be mounted to a vehicle dashboard or center console solely through access to the exposed surface of the interface module. In many existing portable phone mounts, the installer must gain access to the backside of the mounting surface. The interface module of the present invention is designed with multiple apertures that extend through its body to allow easy mounting through the exposed or outer mounting surface. The design conforms to new industry standards for portable phone mounting in vehicles.

In addition to the foregoing improved mounting mechanisms, a need also exists to provide enhanced features to portable phone users as more and more people seek ways to improve productivity in their business and personal lives. Because many people spend a significant amount of time in their cars, improving the functional capabilities of portable phones as used in automobiles will potentially make people more productive while simultaneously making use of the phones more safe. The present invention provides solutions to these problems. First, the vehicle mounting mechanisms allow for hands-free use in an automobile, making driving safer during phone conversations. Hands-free use can be further optimized by connecting the portable phone to a power source to preserve battery life, to simultaneously charge the battery while the phone is in use, and to amplify the audio capabilities of the portable phone by connecting it to external speakers, such as the speakers in the vehicle stereo system, to an external microphone to enhance reception of the user's

voice and to an external antenna for improved reception and less dropped calls. All of these capabilities can be achieved through the electronics provided in the interface module.

In still other embodiments of the present invention other improved capabilities and features can be offered. For example, the interface module can include a microprocessor and memory which can store voice recognition software. Thus, the phone and all of its features can be operated by voice commands rather than manual activation of buttons on the phone key pad. Rather than manually dialing the phone while driving, the user can simply activate the phone through voice commands. This can include accessing a phone number from a phone book stored in the phone's memory, or some other portable electronic device or PDA, and instructing the phone to call the number. The memory can also be used for voice dictation to create letters, memos or to store notes and other thoughts while driving. This kind of memory feature can also be included in the pocket member and function like a portable dictation device. Because the phone and pocket member are detachable from the interface module and therefore portable, the pocket member can be detached from the car and moved to another interface module at home or the office where the memory can be transferred to another device, such as a computer, for further use.

It is also contemplated that the interface module can further include software and processing capabilities for converting voice into text and text into voice. For example, the portable phone can be used for Internet access and information received in an analog or digital text format can be converted into an audio format for the convenience of the user. More specifically, the user could access and receive e-mail messages that can be converted into audio messages while driving. The user could also receive any other information from

the Internet or perform transactions such as buying and selling stock, accessing bank accounts and obtaining credit information., etc. The interface module can also be used to communicate with, or between, PDAs located near and/or remote from the interface module including Internet protocol (IP) capable PDAs. The interface module can also communicate with a data connector port associated with the adaptor or pocket. In the context of vehicle usage, the interface module can operate in the vehicle to obtain or execute vehicle bus diagnostic information.

BRIEF DESCRIPTION OF THE DRAWINGS

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

The following description of the preferred embodiment is made with reference to a portable phone. It should be understood that a portable phone is one example of the type of portable electronic device that can be used with the present invention and that other portable electronic devices could be substituted for the portable phone.

Turning to Figs. 1 and 2, an embodiment of the present portable phone interface system 10 is shown. The primary components are a portable phone 12, a pocket member 14 and an interface module 16. The pocket member 14 has a front shell 18 and a rear shell 20, more easily seen in Figs. 3 and 4. The interface module 16 is also assembled from a front shell 22 and a rear shell 24, as is more easily seen in Figs. 6 and 7.

The portable phone 10 sits within a recess 26 in the front shell 18 of the pocket member 14. In turn, the rear shell 20 of the pocket member 14 is configured to attach to the front shell 22 of interface module 16. Although not shown in the figures, the interface module 16 is primarily intended to be mounted in an automobile where it can be attached to the car's power supply and, perhaps other peripheral devices, including a separate or remote antenna, a microphone, the vehicle audio system, a head set having a microphone and ear

phones, the vehicle ignition, a remote keypad, a control interface or vehicle bus for data access, or any other type of device consistent with enhancing the functionality of the phone for the benefit and safety of the user and others. The present interface system, however, is not solely limited to use in vehicles, but can be utilized in any location where portable electronic devices, including communication devices or portable phones, can be used and primarily in locations with access to a power supply such as home or office. Moreover, the interface module 16 is a universal adapter; it is designed to interface with every pocket member 14 even though the pocket members 14 are designed to interface only with a specific type of portable electronic device, portable phone or other device 12 due to differences in physical design and electrical operation. Thus, even though a pocket member 14 is designed solely to accept a single manufacture's phone and a second pocket member 14 is designed to only accept a different type phone, both pocket members 14 will connect with any interface module 16 due to a common interface.

As shown in Figs. 2 and 3, the front shell 18 of the pocket member 14 includes a pocket or receiving section 26, primarily defined by the side walls 28, the back wall 30 and the base 32, in which a specific type of portable phone is mounted. The side walls 28, back wall 30 and base 32 are designed to receive the body of a specific type of portable phone and therefore would be configured differently for different portable phones. The receiving section 26 further includes a latching mechanism 34 to secure the portable phone when it is seated within the pocket member 14 and a release mechanism (not shown) to disengage the latching mechanism 34 and release the phone 12 from the pocket member 14. Electrical contacts 38 and 40, positioned in the base 32, are designed to mate with the particular

electrical contacts (not shown) of the intended phone 12. As should be appreciated by one skilled in the art, the electrical contacts are configured differently for each different portable phone configuration.

The pocket member 14 serves at least two purposes. First, it mechanically engages the phone and second, it creates an electrical connection between the phone and the interface module 14. The mechanical connection between the phone and the pocket member is illustrated in Figs. 2 and 3. The electrical connection is illustrated in Figs. 3 and 4.

With respect to the electrical connection between the phone and the pocket member, as stated previously, electrical contacts 38 and 40 are positioned in the base 32 of the receiving section 26 of the front shell 18 to contact complementary electrical contacts in the body of the phone 12. An internal flexible cable (not shown) connects the electrical contacts 38 and 40 to a printed circuit board 42 positioned between the front and rear shells 18 and 20. A 30 pin connector 44 is mechanically and electrically mounted to the base of the printed circuit board 42 and a coaxial cable connector 46 is also mechanically mounted to the printed circuit board 42 proximate the 30 pin connector 44 to maintain alignment with the 30 pin connector 44. As most easily seen in Fig. 3, the coaxial connector 46 includes a coaxial cable assembly 36 connected to the coaxial connector 46 at one end and coaxial connector 37 at the opposite end for interconnection to the phone 12. If desired, the internal antenna of the phone can be connected to an external antenna (not shown), such as the antenna for the car radio, by accessing the internal antenna through the coaxial cable assembly 36 or, in some instances, through the electrical contacts 38 or 40, which connection is routed through the coaxial connectors 46 and 48 into the interface module 16

and ultimately connected to the external antenna for enhancing the reception of the phone. The electrical contacts 38 and 40 and the 30 pin connector 44 provide electrical communication with the portable phone. The 30 pin connector 44 allows segregation of and access to various features of the phone such as the phone power supply, battery charge circuitry, serial/digital data transfer circuitry and audio data transfer circuitry, and further allows control signals to be sent to and from the phone for controlling different functions of the phone, such as battery charging, and for enhancing the capabilities of the phone, such as by incorporating voice recognition software and hardware into the interface module which would be activated by commands made into the phone.

As also seen in Figs. 3 and 4, a rectangular aperture 50 is formed in the rear shell 20 of the pocket member in order that the 30 pin connector 44 can extend out of the rear wall of the pocket member 14 and connect to a complementary 30 pin connector 52 in the interface module 16. Similarly, a second aperture 54 is formed in the rear wall of the rear shell 20 in order to allow the coaxial cable connector 46 to extend out of the pocket member 14 and connect to a complementary coaxial cable connector 56 in the interface module 16. The printed circuit board 42 and/or electrical connectors 38 and 40 are further designed to move in both the x and y directions (horizontally and vertically as depicted in the Figures) relative to the apertures 50 and 54 to facilitate connection with the complementary connectors 52 and 56 in the interface module 16. A cover panel 58 allows access to the printed circuit board 42 and is designed to be replaced by a data connector which will be electrically connected to the printed circuit board 42 to further enhance the functionality of

the phone. Of course, it should be understood by those skilled in the art that other types of connectors than those disclosed can be used to accomplish the same results.

A further important feature is the mechanical latching mechanism between the pocket member 14 and the interface module 16. Figs. 3 and 4 show the elements of the pocket member 14 which are involved in the universal or common mechanical connection between the pocket member 14 and the interface module 16. More specifically, in the preferred embodiment, four apertures 60 are formed in the rear wall 62 of the rear shell 20. These apertures 60 are designed to receive four protuberances 64 formed on the face 66 of the front shell 22 of the interface module 16 (see Fig. 5). The protuberances 64 are designed to fit in the apertures 60 and to restrict lateral and longitudinal movement of the pocket member 14 and interface module 16 relative to each other. As illustrated in Fig. 3, on the inside surface 68 of the rear shell 20 of the pocket member 14, each aperture 60 is covered on three sides by a cover or dome 70. As is also shown in Fig. 3, as well as in Figs. 10 and 12-15, channels 72 are formed in the inside surface 68 of the rear shell 20 adjacent and below each aperture 64. The domes 70 are open along the bottom edge, as depicted in Figs. 10 and 12, to provide access to channels 72.

In addition to the alignment provided by the four protuberances 64 engaging the four apertures 60 and domes 70, the outer surface of the rear shell 20 of the pocket member 14 is also configured to assist in mating the pocket member 14 with the interface module 16. As shown in Fig. 4, the rear shell 20 of the pocket member includes a mounting section 74. The mounting section 74, like the protuberances 64 and apertures 60, is identical in all pocket members 14 and is designed to mate with a complementary receiving section 76 on

the front shell 22 of the interface module 16. Similarly, the rear wall 62 of the pocket member 14 includes an angled portion 75 and head portion 77 which cooperate with a raised surface 79 on the front face 66 of the interface module 16 for proper alignment of the two bodies during mechanical connection (Figs. 2, 4 and 6). In this manner, the connection
5 between any pocket member 14 and an interface module 16 will be universal and only one style of interface module will be needed to connect with any of a number of configurations of pocket members.

The mounting section 74 includes a raised body portion 78 generally defined by a laterally extending ridge 80 formed by the side wall 82 of the rear shell 20. The raised body
10 portion 78 has a pair of side walls 84 which merge at a base member 86 extending longitudinally from the raised body portion 78. A second ridge 88 extends outwardly from the base member 86. The rear shell 20 of the pocket member 14 further includes an outwardly extending pin 90. The pin 90 extends into a release hole 92 formed in the front shell 22 of the interface module 16 and, as will be explained in more detail below, activates
15 the latching mechanism 94.

The receiving section 76 of the interface module 16 is also shown in Figs 5 and 6. The receiving section 76 includes a pair of raised flanges or side walls 96 which terminate at the lower portion of the interface module 16 to form a recess 98. The raised flanges 96 are configured to engage the side walls 84 of the raised body portion 78 of the pocket
20 member 14 such that the body portion 78 of the pocket member 14 nests inside the flanges 96 of the interface module 16 and the top edge 100 of the flanges 96 abut the ridge 80 (see Figs. 1 and 4). In addition, the base portion 86 fits within the recess 98 such that the ridge

88 seats itself in the slot 102 formed in the outer surface 66 of the front shell 22 of the interface module 16. This alignment of the mounting section 74 of the pocket member 14 and the receiving section 76 of the interface module 16 further aligns the protuberances 64 with the apertures 60 and the 30 pin connector 44 and coaxial connector 46 with the matching 30 pin connector 52 and coaxial connector 56 in the interface module 16.

As shown in Fig. 6, a printed circuit board 104 is also disposed in the interface module 16. The 30 pin connector 52, which matches the 30 pin connector 44 in the pocket member 14, is electrically and mechanically connected to the printed circuit board 104 at its base. The coaxial connector 56 is mechanically mounted adjacent the printed circuit board 104 by a mounting bracket 57 in the rear shell 24 of the interface module 16. An external coaxial cable (not shown) interconnects an external antenna to the coaxial connector 56 through a port 59 in the rear shell 24 (Fig. 7). These two connectors 52 and 56 extend through a pair of complementary openings 106 and 108 in the front shell 22 of the interface module 16 to connect with the 30 pin connector 44 and coaxial connector 46 of the pocket member. Thus, unlike other portable phone mounts, no external or separate cable is needed to electrically connect the phone to the mounting device.

The configuration of the mechanical connection between the pocket member 14 and the interface module 16 also protects the integrity of the electrical connectors. As should be appreciated from the foregoing description and the accompanying Figures, the pocket member 14 engages the interface module 16 via a limited, one-dimensional movement. In other words, the two components are simply pressed together, without the need of any complex multi-dimensional or rotational movement of one component relative to the other.

Indeed, if a rotational movement were used to separate the pocket member 14 from the interface module 16 once they are engaged, the electrical connectors could be damaged, i.e., the pins could be bent or broken. However, the engagement of the ridge 88 in the slot 102, together with the engagement of the flanges 96 with the side walls 84 of the raised body portion 78 preclude any rotational or two-dimensional movement of the pocket member 14 and interface module 16 relative to each other during installation or removal. This preserves the integrity of the electrical connection and enhances the quality and life of the product.

The internal elements of the interface module 16 include the latching mechanism 94, which locks the interface module 16 to the pocket member 14, and the printed circuit board 104 (see Figs. 6 and 7) which has been previously identified. The printed circuit board 104 includes various electronic componentry for enhancing the usefulness and capabilities of a portable phone. These electric components include, but are not limited to, a microprocessor 110, a power supply 112, a digital signal processor 114 and a cable connector 116 and cable harness 118 for interconnecting the electronics on the printed circuit board 104 with external devices, including a power supply (not shown). Louvered vents 105 are positioned in the rear shell 24 to provide air flow for cooling the various electronic components. The latching mechanism 94 includes a latch plate 120, a plate spring 122, a spacer 124, a rotating lever 126 and a release rod 128. As is explained in greater detail below, the latch plate 120 moves between a first (unlocked or disengaged) position and a second (locked or engaged) position in order to secure the pocket member 14 to the interface module 16.

As further seen in Figs. 6 and 7, the front shell 22 and rear shell 24 of the interface module 16 include four apertures 130 for purposes of receiving screws or other connectors

(not shown) for assembling the interface module 16 and which can also be used for attaching the interface module 16 to the dashboard or seat console in a car. Because the apertures 130 extend through the front and rear shells 22 and 24 of the interface module 16, the interface module 16 may easily be mounted to the dashboard or console with access only to the front shell 22. Therefore, unlike other devices, the interface module 16 is not mounted solely via access to the rear shell 24.

The inside surface 132 of the rear shell 24 has an inwardly extending hollow rear post 134 adjacent each aperture 130. Each aperture 130 in the front shell 22 similarly has an adjacent hollow front post 136 extending into the interface module 16. The rear posts 134 extend through four apertures 138 in the printed circuit board 104. The four front posts 136 extend around the latch plate 120, through the bushings 140 in the spacer 124, through an opening 142 in the rotating lever 126 and seat inside the rear posts 134. The spacer 124 separates the latching mechanism 120 from the printed circuit board 104 and secures the latching mechanism against the front shell 22.

As also seen in Figs. 6 and 7, the latch plate has four latch tabs 144, a release tab 146 and a spring tab 148. The plate spring 122 is positioned between the upper edge 150 of the latch plate 120 and a spring restraint 152 formed on the inside surface of the front shell 22 (see Fig. 8). When fully assembled, the spring tab 148 sits inside a plate spring 122. Because the plate spring 122 is in compression, it applies a downward force against the latch plate 120, as depicted in Figs. 6 and 7. The inside surface of the front shell 22 of the interface module 16 also includes a release tab shelf 154. The release tab shelf 154 is positioned adjacent the pin release hole 92 formed in the front shell 22. The latching tabs

144 extend forward from the plane of the latch plate 120 and, although not readily discernable from the Figures, in the preferred embodiment each latching tab 144 is separated or offset from the latch plate 120 at a different distance than the others (see Fig. 15). When the interface module 16 is fully assembled, the latch tabs 144 are positioned in the protuberances 64.

To activate the latching mechanism 94 and lock the interface module 16 to the pocket member 14, the latch plate 120 moves between a first and second position. In the first position or the unlocked position, the release tab 146 rests against the release tab shelf 154 and the protuberances 64 are seated inside the recesses 60 and domes 70 of the pocket member 14 so that the latch tabs 144 are positioned adjacent and above the opening 156 in the protuberances 64. The latch plate 120 is moved to the second position, or the locked position, by the pin 90 extending into the pin release hole 92 as the pocket member 14 is moved into physical engagement with the interface module 16 (Figs. 9 and 11). This limited, one-dimensional motion forces the release tab 146 off of the release tab shelf 154 (Fig. 11). When the release tab 146 is no longer engaged by the release tab shelf 154, the plate spring 122 forces the latch plate 120 downwardly as depicted in the Figures to a second or locked position. In moving to the second position, the latch tabs 144 move out of the openings 156 and engage the channels 72 in wall 68 of the rear section 20 of the pocket member 14 (Figs. 10 and 12-14).

Premature activation of the latching mechanism prior to the pocket member 14 being seated squarely in the interface module 16 is avoided because of the alignment provided by the mounting section 74, angled portion 75 and head portion 77 of the pocket member, the

receiving section 76 and raised portion 79 of the interface module. Each of the involved members compel proper alignment of the pocket member relative to the interface module such that the protuberances 64 are fully positioned in the apertures 60 prior to the release pin 90 activating the locking mechanism 94.

5 In the preferred embodiment, because each latch tab 144 is slightly offset from the others relative to the plane of the latch plate 120, they engage the channels 72 consecutively rather than simultaneously. In this way, less force needs to be applied to fully engage the latch tabs 144 with the channels 72 and to lock the pocket member 14 to the interface module 16 (Fig. 15). Moreover, the plate spring 122 only has to have sufficient force to move the
10 latch plate 120 to the locked position. Once the latch plate 120 and latch tabs 144 are in the locked position, the latch tabs 144 maintain the engagement between the pocket member 14 and interface module 16. Indeed, the latch tabs 144 are designed and configured to draw the pocket member into the interface module and substantially eliminate any manufacturing tolerances which would cause either component to move relative to the other. The fact that
15 the latch tabs 144 are offset in the preferred embodiment also allows the latching mechanism 94 to eliminate manufacturing tolerances. It will also be observed that the latch tabs 144 have a curved profile. This shape enhances the ability of the latch tabs 144 to secure the pocket member 14 to the interface module 16, although persons of skill in the art will appreciate different shapes that can be utilized. In addition, the latch tabs 144 are designed
20 with sufficient resiliency that should the pocket member be physically pulled from the interface module without disengaging the latching mechanism, overcoming the safety force

designed to hold the two components together, the latch tabs will return to their normal shape and continue to function properly.

Figs. 6, 7, 16 and 17 illustrate the various components that comprise the release mechanism for moving the locking mechanism 94 from the locked position to the unlocked position in order to disengage the pocket member 14 from the interface module 16. The release rod 128 slides along the side wall 158 of the rear shell 24 of the interface module 16 and within an aperture 160 formed by the front shell 22 and rear shell 24. A pair of outwardly biased springs 162, having enlarged ends 164, are formed in opposite sides of the release rod 128 and contact the inside surface 158 of the rear shell 24 to dampen any rattling of the release rod 128. As best seen in Figs. 16 and 17, the release rod 128 is attached to the lever 126 by a pin 166 positioned at one end of the lever 126. The pin 166 sits in a slot 168 formed in the base of the release rod 126. The lever 126 has a central aperture 142 which allows it to pivot about one of the posts 136 formed on the inside surface of the front shell 22 of the interface module 16. Also mounted to the lever body 126, opposite the pin 166, are a pair of posts 170 and 172 with a gap formed between them. A release flange 174 formed along the upper edge of the latch plate 120 is positioned in the gap between the posts 170 and 172 when the interface module 16 is assembled (see Figs. 16 and 17).

To move the latch plate 120 and disengage the latching mechanism 94 from the pocket member 14, the release rod 128 is pressed. This action causes the lever 126 to rotate about the post 136, which in turn forces the lower post 172 to engage the release flange 174 and move the latch plate 120 to the unlocked position. Because the release tab 146 is biased toward the release tab shelf 154, when the release tab 146 is adjacent the shelf 154, the

release tab 146 will move into engagement with the shelf 154, will push the pin 90 out of the pin release hole 92, and secure the latch plate 120 in the unlocked position. This action will also cause the plate spring 122 to compress. By moving the latch plate 120 from the second (locked) position to the first (unlocked) position, the latch tabs 144 will retract from the channels 72 in the rear shell 20 of the pocket member 14 and into the protuberances 64 of the front shell 22 of the interface module 16 allowing the pocket member 14 to be removed from the interface module 14 with a limited, one-dimensional motion.

It should also be noted that the release rod 128 may have a hollow configuration for ventilation purposes. As a hollow member, it acts as a chimney, in combination with louvered vents 105, to remove heat from inside the interface module thereby cooling the internal electronic components.

As should be appreciated, the present invention provides a mounting and support system for portable phones which optimizes the space needed to achieve mounting. With a one-dimensional, limited motion the phone and pocket member can be attached to the interface module. Moreover, while an exemplary and preferred embodiment has been described, those having skill in the art will recognize various changes, modifications, additions and applications other than those expressly identified. Such changes, additions, modifications and additional applications are within the scope of the present invention.
